Dumps Analysis, Generated by Codex 🤖

On operational monitoring in SAP and LLM analysis

Lars Hvam Petersen ✓

Senior SAP/ABAP Consultant at Heliconia Labs

July 18, 2026

Monitoring ST22 dumps and database performance in SAP systems is typically manual in many organizations. And code is cheap, so its easy to write a REST endpoint, persist data in some tables, and connect LLMs to your productive system via a MCP server!

Solved? Perhaps.

Perhaps the easy and fast solution is the most expensive for your organization? Who manages and checks authorizations, what if the LLM does a denial of service attack?

Before starting development(asking the LLM to build it), consider what options there are, and what adds the most value for your organization, and what are the compromises?

Send the telemetry to an observability platform

One other option is sending the telemetry to an observability platform, that way, the data only goes one way(out of the system), which opens much less questions about security and scalability.

Your organization might already have an observability platform(Grafana or Elastic or similar) in the landscape that ingests [OpenTelemetry](#) data. The data is moved out of the HANA database allowing long term trend

analysis(which is typically built into these tools), and doesn't increase memory usage in the HANA db.

And its possible to get visibility on how your entire stack operates, SAP and non-SAP systems.

Heck, even vibe code a observability platform if you don't have one.

Visibility comes first, allow users to easily access the data, then connecting an LLM becomes easy too.
